

A First Qualitative Comparison of the Admission Control in FTT-SE, HaRTES and AVB

Inés Álvarez, Luís Almeida, Julián Proenza

Introduction

- Ethernet is gaining importance in automation, avionics and automotive.
- Multimedia & control traffic coexistence.
- Diversity in size, intensity and timing of the traffic.
- Ethernet lacks for real-time and adaptivity.
- Flexible Time-Triggered and Audio Video Bridging.
- Admission control is provides adaptivity.

In this paper we compare FTT and AVB Admission Control mechanisms in mono-hop networks.

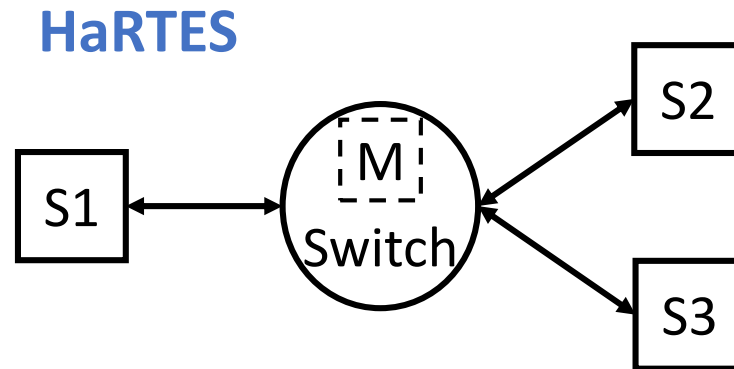

Flexible Time-Triggered

- **Time-triggered** (synchronous) and **event-triggered** (asynchronous) traffic.
- Master/multi-slave architecture.
- Communication done through **streams**.
- Any slave can request the creation of streams.

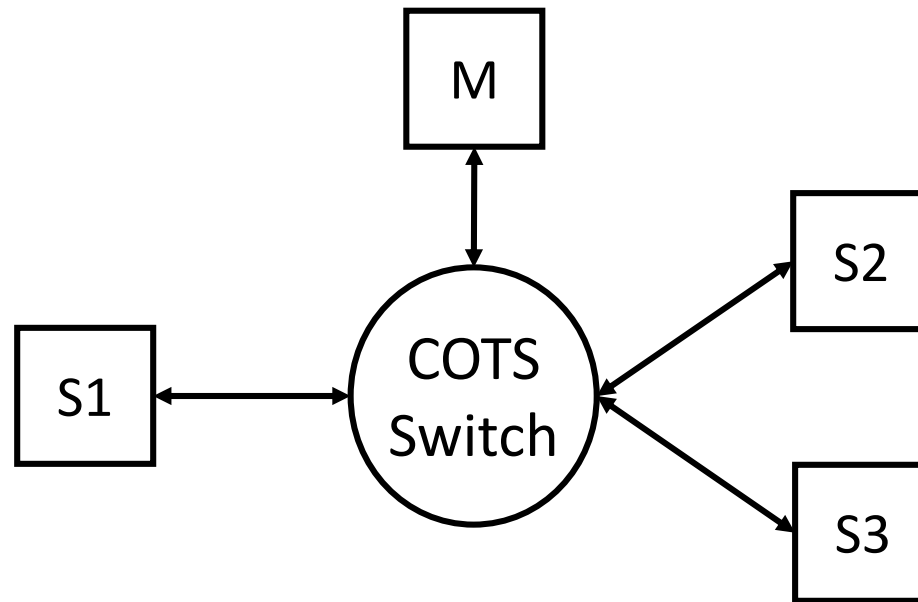

Flexible Time-Triggered

- **Time-triggered** (synchronous) and **event-triggered** (asynchronous) traffic.
- Master/multi-slave architecture.
- Communication done through **streams**.
- Any slave can request the creation of streams.

FTT - Switched Ethernet

Master and slaves connected through a COTS switch.

FTT - Switched Ethernet

Admission control: signalling of requests.

FTT - Switched Ethernet

Admission control: signalling of requests.

Abstract

Ethernet is gaining importance in fields such as automation, avionics and automotive. In these fields novel multimedia-based applications must coexist with traditional control systems, which leads to **high diversity in size, intensity and timing requirements of the traffic traversing the channel**.

Multimedia traffic is characterised by having large size, low intensity and soft real-time requirements, while **control traffic** usually conveys small amounts of information with a high intensity and hard real-time requirements. Moreover, many modern applications must **support on-line connection and disconnection of participants**.

Since **Ethernet** was designed as a general purpose data network protocol it **lacks appropriate support for real-time communications and dynamic quality of service management**. Several protocols were proposed to cope with these drawbacks, including **Flexible Time-Triggered Switched Ethernet** and, more recently, **Audio Video Bridging**.

In this paper we discuss the importance of the admission control and make a comparison of the implementations carried out in the aforementioned protocols.

Audio Video Bridging

AVB is a set of standards that provide Ethernet with synchronisation, frame forwarding and admission control.

The communication is done through virtual channels called **streams**, to which nodes can attach as **talker or listeners**.

The creation of a stream is triggered by the talker and is completed when the talker receives the confirmation of at least one listener.

The **reservation of resources** is done by the switch.

Messages exchanged in Admission Control

Flexible Time-Triggered

Flexible Time-Triggered supports event and time-triggered traffic in a flexible manner. Follows a **master/multi-slave architecture**. The master organises the communication in slots of fixed duration called **Elementary Cycles**, by sending the so called **Trigger Message** to synchronise and trigger the communication among slaves.

The communication is carried out through virtual communication channels called **message streams**. First slaves ask for the creation of the stream and afterwards ask to attach as **publisher or subscribers**.

FTT-SE

Mono-hop Architecture

Messages exchanged in Admission Control

- The slave **informs the master** about the **pending requests**.
- When allowed, the slave **requests the creation or attachment to a stream**.
- The **master performs the admission control** and sends the result to all slaves.

HaRTES

Mono-hop Architecture

Messages exchanged in Admission Control

- The slave **requests to the master the creation and attachment to a stream**.
- The **master checks the availability of resources** and sends the result to all slaves.

Analysis of the performance, flexibility and reliability of the admission control

Performance

Number of messages needed for the creation of a stream with a transmitter and a receiver

Flexibility

Functionalities provided by the admission control

- | FTT-SE | HaRTES | AVB |
|---|---|--|
| <ul style="list-style-type: none"> Several classes of traffic: Hard and soft real-time. On-line connection and disconnection of participants. Changing QoS requirements of a stream on-line. Legacy nodes: use of non-FTT-aware applications. | <ul style="list-style-type: none"> Several classes of traffic: Hard and soft real-time. On-line connection and disconnection of participants. Changing QoS requirements of a stream on-line. Legacy nodes: use of non-FTT-aware applications. | <ul style="list-style-type: none"> Several classes of traffic: Class A and B, soft real-time with different timing guarantees. On-line connection and disconnection of participants. |

Reliability

Level of tolerance to errors affecting the admission control

FTT-SE HaRTES AVB

Temporary faults affecting the channel

- | | | |
|--|---|---|
| <p>Signaling message: delay AC</p> <p>Request message: prevent AC</p> <p>Command message: missed resources + inconsistency</p> | <p>Request message: prevent AC</p> <p>Command message: missed resources + inconsistency</p> | <p>Talker advertise: prevent AC</p> <p>Listener ready: prevent communication.</p> |
|--|---|---|

Permanent faults → single points of failure in the architecture

Conclusions and Future Work

Reliability: none of the protocols provide adequate services to face transient faults; HaRTES is currently the only one handling permanent faults; IEEE is developing a new set of standards to overcome some of these problems.

Flexibility: FTT allows to dynamically change the QoS of the streams and the use of legacy nodes, conversely to AVB.

Performance: FTT-SE introduces a significant overhead in the communication channel when compared to HaRTES and AVB.

	Reliability		Flexibility			Performance
	Transient Faults	Permanent Faults	QoS change	Class change	Legacy nodes	Overhead ¹
FTT-SE	x	x	x	x	x	12
HaRTES	x	x	x	x	x	4
AVB	x	x	x	x	x	4

We are currently working on extending this comparison and carrying out a quantitative one, through simulation in OMNeT++.
